#Rcpp

We will get some experience with speeding up R code using C++ via the Rcpp package.

First, clear the workspace and load the Rcpp package.

```
pacman::p_load(Rcpp)
```

Create a variable n to be 10 and a vaiable Nvec to be 100 initially. Create a random vector via rnorm Nvec times and load it into a Nvec x n dimensional matrix.

```
n <- 10
Nvec <- 100
X = matrix(data=rnorm(Nvec * n), nrow=Nvec)
head(X)</pre>
```

```

```

Write a function all_angles that measures the angle between each of the pairs of vectors. You should measure the vector on a scale of 0 to 180 degrees with negative angles coerced to be positive.

```
angle <- function(u, v){
  acos(sum(u * v)/sqrt(sum(u^2)*sum(v^2)))
}

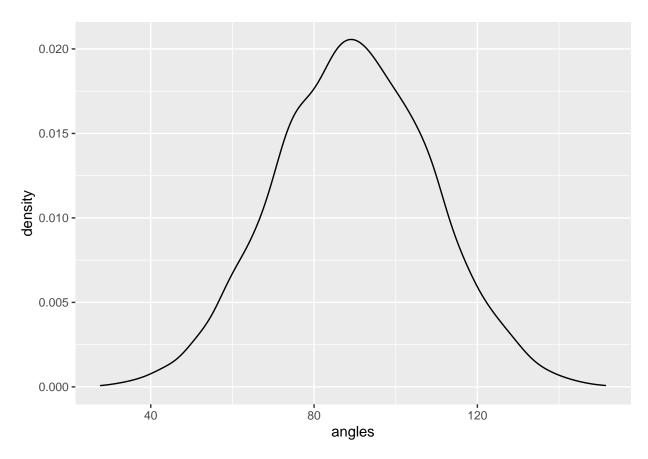

all_angles <- function(X) {
  A = matrix(NA, nrow = nrow(X), ncol = nrow(X))
  for(i in 1:(nrow(X) - 1)){</pre>
```

```
for(j in (i+1):nrow(X)){
    A[i,j] = angle(X[i,], X[j,]) * (180/pi)
    }
}
A
}
#all_angles(X)
```

Plot the density of these angles.

```
pacman::p_load(ggplot2)
ggplot(data.frame(angles = c(all_angles(X)))) +
  aes(x = angles) +
  geom_density()
```

Warning: Removed 5050 rows containing non-finite values (stat_density).

Write an Rcpp function all_angles_cpp that does the same thing. Use an IDE if you want, but write it below in-line.

```
cppFunction('
  NumericMatrix all_angles_cpp(NumericMatrix X) {
  int n = X.nrow();
```

```
int p = X.ncol();
   NumericMatrix A(n, n);
    std::fill(A.begin(), A.end(), NA_REAL);
    for (int i_1 = 0; i_1 < (n - 1); i_1 + + \}
      //Rcout << "computing for row #: " << (i_1 + 1) << "\\n";
      for (int i_2 = i_1 + 1; i_2 < n; i_2++){
        double sum_sqd_u = 0;
        double sum sqd v = 0;
        double sum_u_v = 0;
        for (int j = 0; j < p; j++){
          sum_sqd_u += pow(X(i_1, j), 2);
          sum_sqd_v += pow(X(i_2, j), 2);
          sum_uv = X(i_1, j) * X(i_2, j);
          //acos(sum(u * v)/sqrt(sum(u^2)*sum(v^2)))
          acos(sum_u_v/sqrt(sum_sqd_u * sum_sqd_v)) * (180/M_PI);
        A(i_1, i_2) = acos(sum_u_v/sqrt(sum_sqd_u * sum_sqd_v)) * (180/M_PI);
   }
   return A;
  ')
#all_angles_cpp(X)
```

Test the time difference between these functions for n = 1000 and Nvec = 100, 500, 1000, 5000 using the package microbenchmark. Store the results in a matrix with rows representing Nvec and two columns for base R and Rcpp.

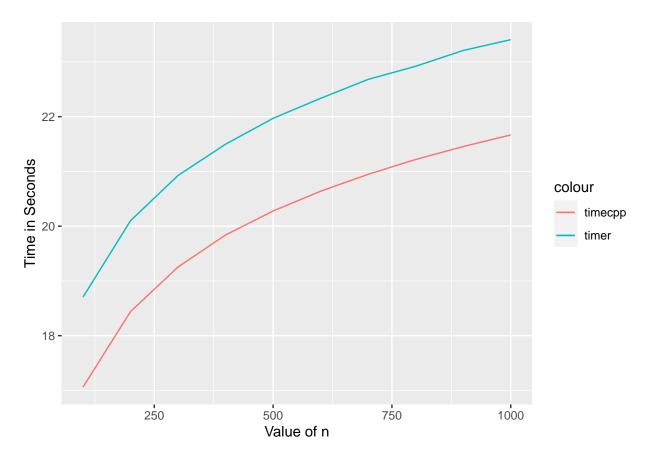

```
pacman::p_load(microbenchmark)

n <- 1000
Nvec <- c(100, 200, 300, 400, 500, 600, 700, 800, 900, 1000)
time_r <- c()
time_cpp <- c()
for (i in 1:length(Nvec)){
    X <- c()
    for (j in 1:n){
        x <- rnorm(Nvec[i])
        X <- cbind(X, x)
    }
    time_r <- c(time_r, mean(microbenchmark(angles_r = all_angles(X), times = 3, unit = "s")$time))
    time_cpp <- c(time_cpp, mean(microbenchmark(angles_cpp = all_angles_cpp(X), times = 3, unit = "s")$time})</pre>
```

Plot the divergence of performance (in log seconds) over n using a line geometry. Use two different colors for the R and CPP functions. Make sure there's a color legend on your plot. We will see later how to create "long" matrices that make such plots easier.

```
pacman::p_load(ggplot2)
ggplot() +
  geom_line(aes(x = Nvec, y = log(time_r), col = "timer")) +
  geom_line(aes(x = Nvec, y = log(time_cpp), col = "timecpp")) +
```

```
xlab("Value of n") +
ylab("Time in Seconds")
```

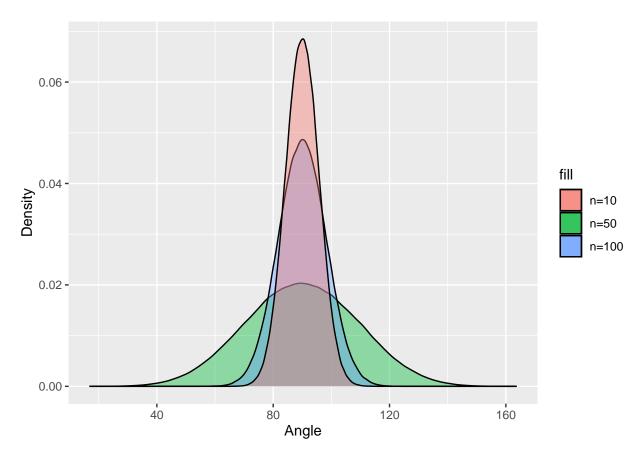

Let Nvec = 10000 and vary n to be 10, 100, 1000. Plot the density of angles for all three values of n on one plot using color to signify n. Make sure you have a color legend. This is not easy.

```
Nvec = 1000
X \leftarrow c()
for (i in 1:10){
  x <- rnorm(Nvec)
  X \leftarrow cbind(X, x)
ang1 <- all_angles(X)</pre>
X <- c()
for (i in 1:50){
  x <- rnorm(Nvec)
  X \leftarrow cbind(X, x)
ang2 <- all_angles(X)</pre>
X <- c()
for (i in 1:100){
  x <- rnorm(Nvec)
  X \leftarrow cbind(X, x)
ang3 <- all_angles(X)</pre>
```

```
ggplot() +
  geom_density(aes(x = ang1, fill = "red"), alpha = .4) +
  geom_density(aes(x = ang2, fill = "yellow"), alpha = .4) +
  geom_density(aes(x = ang3, fill = "green"), alpha = .4) +
  scale_fill_discrete(labels = c("n=10", "n=50", "n=100")) +
  ylab("Density") +
  xlab("Angle")
```

- ## Warning: Removed 500500 rows containing non-finite values (stat_density).
- ## Warning: Removed 500500 rows containing non-finite values (stat_density).
- ## Warning: Removed 500500 rows containing non-finite values (stat_density).

Write an R function nth_fibonnaci that finds the nth Fibonnaci number via recursion but allows you to specify the starting number. For instance, if the sequence started at 1, you get the familiar 1, 1, 2, 3, 5, etc. But if it started at 0.01, you would get 0.01, 0.01, 0.02, 0.03, 0.05, etc.

```
nth_fibonacci <- function(n, start){
  if (n == 1 | n == 2) return(start)
  else return(nth_fibonacci(n-1, start) + nth_fibonacci(n-2, start))
}
nth_fibonacci(8, 1)</pre>
```

[1] 21

Write an Rcpp function nth_fibonnaci_cpp that does the same thing. Use an IDE if ou want, but write it below in-line.

```
cppFunction(
  'double nth_fibonacci_cpp(int n, double start){
    if (n == 1 || n == 2) return start;
    else return (nth_fibonacci_cpp(n-1, start) + nth_fibonacci_cpp(n-2, start));
    }'
)
nth_fibonacci_cpp(8, 1)
```

[1] 21

Time the difference in these functions for $n = 100, 200, \ldots, 1500$ while starting the sequence at the smallest possible floating point value in R. Store the results in a matrix.

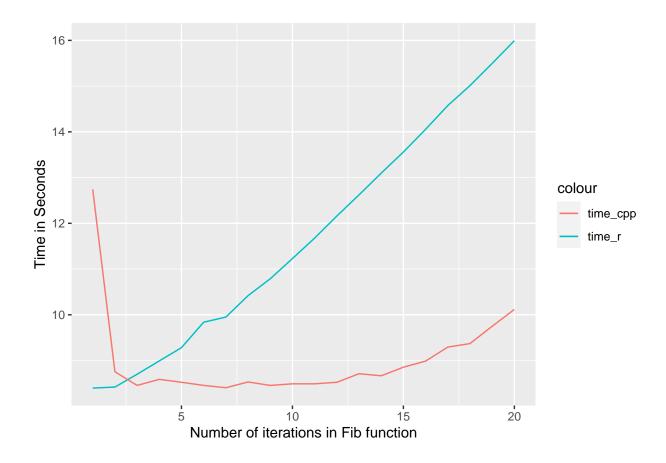

```
n = 20

time_r <- c()
time_cpp <- c()

for (i in 1:n){
   time_r <- c(time_r, mean(microbenchmark(fib_r = nth_fibonacci(i, .Machine$double.xmin), times = 3, un
   time_cpp <- c(time_cpp, mean(microbenchmark(fib_cpp = nth_fibonacci_cpp(i, .Machine$double.xmin), tim
}</pre>
```

Plot the divergence of performance (in log seconds) over n using a line geometry. Use two different colors for the R and CPP functions. Make sure there's a color legend on your plot.

```
ggplot() +
  geom_line(aes(x = 1:n, y = log(time_r), col = "time_r")) +
  geom_line(aes(x = 1:n, y = log(time_cpp), col = "time_cpp")) +
  xlab("Number of iterations in Fib function") +
  ylab("Time in Seconds")
```

Data Wrangling / Munging / Carpentry

Throughout this assignment you can use either the tidyverse package suite or data.table to answer but not base R. You can mix data.table with magrittr piping if you wish but don't go back and forth between tbl_df's and data.table objects.

```
pacman::p_load(tidyverse, magrittr, data.table)
```

Load the storms dataset from the dplyr package and investigate it using str and summary and head. Which two columns should be converted to type factor? Do so below.

```
data(storms)
head(storms)
```

```

## # ... with 406 more rows, and 2 more variables: ts_diameter <dbl>,
       hu_diameter <dbl>
```

Create a new feature wind_speed_per_unit_pressure.

```
storms %<>%
mutate(wind_speed_per_unit_pressure = wind/pressure)
```

Create a new feature: average_diameter which averages the two diameter metrics. If one is missing, then use the value of the one that is present. If both are missing, leave missing.

For each storm, summarize the maximum wind speed. "Summarize" means create a new dataframe with only the summary metrics you care about.

```
storms %>%
group_by(name) %>%
summarize(maximum_wind_speed = max(wind, na.rm = TRUE))
```

```

```

For each named storm, find its maximum category, wind speed, pressure and diameters (do not allow the max to be NA) and the number of readings (i.e. observations).

Calculate the distance from each storm observation to Miami in a new variable distance_to_miami. This is very challenging. You will need a function that computes distances from two sets of latitude / longitude coordinates.

```
MIAMI_LAT_LONG_COORDS = c(25.7617, -80.1918)
distance <- function(lat1, long1, lat2, long2){</pre>
  lat1 = lat1 * 180/pi
  lat2 = lat2 * 180/pi
 long1 = long1 * 180/pi
  long2 = long2 * 180/pi
  # Haversine formula
  a = \sin(1at2 - 1at1 / 2)^2 + (\cos(1at2) * \cos(1at1)) * \sin(1ong2 - 1ong1 / 2)^2
  b = 2 * atan2(sqrt(a), sqrt(1 - a))
 distance = 6373.0 * b # Multiplying by radius of earth in KM
  return(distance)
}
storms %>%
 mutate(distance to miami = distance(lat, long, MIAMI LAT LONG COORDS[1], MIAMI LAT LONG COORDS[2]))

```

For each storm, find the total distance it moved over its observations and its total displacement. "Distance" is a scalar quantity that refers to "how much ground an object has covered" during its motion. "Displacement" is a vector quantity that refers to "how far out of place an object is"; it is the object's overall change in position.

```

Is there a relationship between average ground speed and maximum category attained? Use a dataframe summary (not a regression).

```
speed_and_category <- storms %>%
  group_by(name) %>%
  summarize(avg_ground_speed = mean(speed), maximum_category = as.numeric(max(category)))
cor(speed_and_category[,2], speed_and_category[,3])
```

```
## maximum_category
## avg_ground_speed 0.2531993
```

Now we want to transition to building real design matrices for prediction. This is more in tune with what happens in the real world. Large data dump and you convert it into X and y how you see fit.

Suppose we wish to predict the following: given the first three readings of a storm, can you predict its maximum wind speed? Identify the y and identify which features you need $x_1, ... x_p$ and build that matrix with dplyr functions. This is not easy, but it is what it's all about. Feel free to "featurize" as creatively as you would like. You aren't going to overfit if you only build a few features relative to the total 198 storms.

A tibble: 6 x 6

```
y max_category pressure speed total_distance_traveled status

Fit your model. Validate it.

```
# OLS model
n = nrow(storms_data)
K = 5 \# 1/5 of data will be set to the testing set
test_indices = sample(1 : n, 1 / K * n)
train_indices = setdiff(1:n, test_indices)
X = select(storms_data, -y)
y = storms_data$y
X_test = X[test_indices,]
y_test = y[test_indices]
X_train = X[train_indices,]
y_train = y[train_indices]
mod = lm(y_train ~ ., data.frame(X_train))
is_Rsq = summary(mod)$r.squared #in-sample R^2
is_RMSE = sqrt(mean((mod$residuals)^2)) #in sample RMSE
y_hat_oos = predict(mod, data.frame(X_test))
oos_residuals = y_test - y_hat_oos #oos e's
oos_Rsq = 1 - sum(oos_residuals^2) / sum((y_test - mean(y_test))^2) #oos_R^2
oos_RMSE = sqrt(mean((oos_residuals)^2)) #oos RMSE
validations = data.frame(Metric = c("In Sample R-squared:", "In Sample Standard Error:",
                                     "OOS R-squared:", "OOS Standard Error:"),
                         Value = c(is_Rsq, is_RMSE, oos_Rsq, oos_RMSE))
validations
```

Assess your level of success at this endeavor.

Metric Value In Sample R-squared: 0.9767775

In Sample RMSE: 5.2338984 OOS R-squared: 0.9655298 OOS RMSE: 6.0078328

These are the metrics the model achieved after a first run. The objective was to predict the maximum wind speed of a storm based on a few causal features. According to the out of sample RMSE metric, the model

could predict the maximum wind speed of a storm with a margin of +- 6.00 knots. Considering the storms can range with wind speeds between 15 and 160 knots, for the model to make predictions with such a margin makes this an adequate model. The model achieved an Rsq score of 0.97 with only 5 features, meaning the features are explaining the variance within y very well. This model is clearly a very good model. To calculate more accurate metrics we could cross validate, I will not because I am lazy.

The Forward Stepwise Procedure for Probability Estimation Models

Set a seed and load the adult dataset and remove missingness and randomize the order.

```
set.seed(420)
pacman::p_load_gh("coatless/ucidata")
data(adult)
adult = na.omit(adult)
adult = adult[sample(1 : nrow(adult)), ]
```

Copy from the previous lab all cleanups you did to this dataset.

adult\$status = as.factor(adult\$status)

adult$worktype = as.character(adult$worktype)
adult$worktype = ifelse(adult$worktype \( \frac{100}{100} \)), "Other", adult$worktype (tab_worktype (100)), "Other", adult$worktype (100))
adult$worktype = as.factor(adult$worktype)
adult$status = paste(as.character(adult$relationship), as.character(adult$marital_status), sep = ":")
adult$status = as.character(adult$status)
tab_status = sort(table(adult$status))
adult$relationship = NULL
adult$marital_status = NULL
```

We will be doing model selection. We will split the dataset into 3 distinct subsets. Set the size of our splits here. For simplicitiy, all three splits will be identically sized. We are making it small so the stepwise algorithm can compute quickly. If you have a faster machine, feel free to increase this.

```
Nsplitsize = 1000
```

Now create the following variables: Xtrain, ytrain, Xselect, yselect, Xtest, ytest with Nsplitsize observations. Binarize the y values.

```
Xtrain = adult[1 : Nsplitsize, ]
Xtrain$income = NULL
ytrain = ifelse(adult[1 : Nsplitsize, "income"] == ">50K", 1, 0)
Xselect = adult[(Nsplitsize + 1) : (2 * Nsplitsize), ]
Xselect$income = NULL
yselect = ifelse(adult[(Nsplitsize + 1) : (2 * Nsplitsize), "income"] == ">50K", 1, 0)
Xtest = adult[(2 * Nsplitsize + 1) : (3 * Nsplitsize), ]
Xtest$income = NULL
ytest = ifelse(adult[(2 * Nsplitsize + 1) : (3 * Nsplitsize), "income"] == ">50K", 1, 0)
```

Fit a vanilla logistic regression on the training set.

```
logistic_mod = glm(ytrain ~ ., Xtrain, family = binomial(link = logit))
```

Warning: glm.fit: fitted probabilities numerically 0 or 1 occurred

and report the log scoring rule, the Brier scoring rule.

```
p_hat_train = predict(logistic_mod, Xtrain, type = 'response')
#in sample log scoring rule
mean(ytrain * log(p_hat_train) + (1 - ytrain) * log(1 - p_hat_train))
```

```
## [1] -0.2850053
```

```
#in sample Brier scoring rule
mean(-(ytrain - p_hat_train)^2)
```

```
## [1] -0.08957935
```

We will be doing model selection using a basis of linear features consisting of all first-order interactions of the 14 raw features (this will include square terms as squares are interactions with oneself).

Create a model matrix from the training data containing all these features. Make sure it has an intercept column too (the one vector is usually an important feature). Cast it as a data frame so we can use it more easily for modeling later on. We're going to need those model matrices (as data frames) for both the select and test sets. So make them here too (copy-paste). Make sure their dimensions are sensible.

```
Xmm_train = data.frame(model.matrix( ~ . , Xtrain))
Xmm_select = data.frame(model.matrix( ~ . , Xselect))
Xmm_test = data.frame(model.matrix( ~ . , Xtest))
dim(Xmm_train)
```

```
## [1] 1000 93
dim(Xmm_select)
## [1] 1000 93
dim(Xmm_test)
## [1] 1000 93
```

Write code that will fit a model stepwise. You can refer to the chunk in the practice lecture. Use the negative Brier score to do the selection. The negative of the Brier score is always positive and lower means better making this metric kind of like s_e so the picture will be the same as the canonical U-shape for oos performance.

Run the code and hit "stop" when you begin to the see the Brier score degrade appreciably oos. Be patient as it will wobble.

```
pacman::p_load(Matrix)
p_plus_one = ncol(Xmm_train)
predictor_by_iteration = c() #keep a growing list of predictors by iteration
in_sample_brier_by_iteration = c() #keep a growing list of briers by iteration
oos_brier_by_iteration = c() #keep a growing list of briers by iteration
i = 1
